B. J. Malone, P. Eng.

ACKNOWLEDGEMENTS

The Project Staff of the Hamilton Traffic Department wish to express their appreciation to the members of the Regional Engineering Department, the Regional Police Department and the Provincial Judges Court for their co-operation and assistance in the conduct of this study.

The Project Staff would also like to acknowledge the efforts of Mrs. W. Crevier, Mrs. L. Harvey, Mr. T. Hardy, Mrs. C. Buchackert, Mrs. P. Pauls, of the Traffic Department; Mr. J. Speyker and the Staff of the Services Department; and Members of the Systems Division of the Hamilton Treasury Department for their assistance in the preparation of this report.

1985 HAMILTON-WENTWORTH MOTOR VEHICLE COLLISION REPORTIntroduction

This annual report is a summary of factors associated with traffic collisions that occurred in the Regional Municipality of Hamilton-Wentworth in 1985.

The Regional Municipality of Hamilton-Wentworth is situated in southern Ontario, at the westerly end of Lake Ontario. The following Municipalities are located within the Region: The Town of Ancaster, The Town of Dundas, The Township of Flamborough, The Township of Glanbrook, The City of Hamilton and the City of Stoney Creek. The total population of these combined localities was 421,264 in 1985.

Traffic collisions are a primary cause of accidental deaths (Appendix Exhibits A-1, A-2, and A-3), injuries and associated property losses. The intention of this report is to provide factual information to those agencies and persons concerned with the safety of the roadway transportation system within the Regional Municipality of Hamilton-Wentworth.

Traffic collisions frequently involve complex interactions between human behavior, vehicle characteristics, and the environment. The factor or factors responsible for causing a collision are not always the most obvious nor are they always readily apparent. Caution should be exercised in drawing conclusions from the statistics presented in this report and conclusions should be drawn only with appropriate qualifications and supportive information.

The information recorded in this report is based primarily upon motor vehicle accidents investigated by the Hamilton-Wentworth Regional Police. Information about accidents recorded by other police forces, (such as the Ontario Provincial Police) has not been included. This generally excludes incidents occurring on King's Highways (including the Queen Elizabeth Way) that pass through the Region.

1985 HAMILTON-WENTWORTH COLLISION REPORT

Executive Summary:

* In 1985, 7,346 reportable traffic collisions occurred on municipal roadways in the Region of Hamilton-Wentworth. These collisions resulted in:-

- 23 driver or passenger fatalities (9 motor vehicle drivers, 4 motorcyclists, 2 bicyclists and 8 riders or passengers)
- 3 pedestrian fatalities
- 4,119 driver, bicyclist or passenger injuries
- 408 pedestrian injuries
- 21,405 persons (equal to approximately 5 percent of the Regional population) being involved in a reportable traffic collision in 1985
- approximately 17.4 million dollars in property damages (as estimated at the time of the collision)
- 46 million dollars (estimated) in damages when all collision costs including medical costs, loss of income and other related costs are taken into account (see Note 2.3)

* The overall frequency of collisions in Hamilton-Wentworth is generally lower than other major Canadian municipalities.

* The overall frequency rates of fatalities in the City of Hamilton are generally lower than other Canadian and U.S. cities of similar population.

* The period from 12 midnight to 5 a.m. exhibits the highest ratio of collisions to vehicle volume using the street system.

* The greatest causes of traffic collisions were driver or pedestrian error; either errors in judgement or perception, or non-observance of traffic regulations.

* The predominant improper driver actions indicated in collisions were "following too close" and "failure to yield right-of-way".

* Drivers under 20 years of age were involved in a disproportionate number of collisions relative to the number of drivers in this age group that are licenced to drive. This age group was involved in 9.5 percent of the reported collisions although it comprises only 5.5 percent of the licenced driving population.

* 8.8 percent of reported collisions involved one or more drivers who had been drinking.

* Alcohol was associated with a high proportion of collisions (42 percent) which occurred in the hours between 10 p.m. and 3 a.m. from Wednesdays to Sundays and in night-time collisions (21.5 percent of collisions between 6 p.m. and 6 a.m.).

Note: These figures are indicative of alcohol being present in the bloodstream of one or more of the drivers involved in the collision and do not necessarily suggest that alcohol was the proximate cause of the collision.

* Non-licenced drivers were less likely to be driving properly, and more likely to be under the influence of alcohol or drugs when involved in a collision.

* Motorcycle operators were more likely to be driving properly at the time of the collision and more likely to receive injuries if involved in a traffic collision.

* Children between 5 and 9 years of age were involved in a disproportionate number of pedestrian collisions (21.1%) compared with their proportion of the regional population (6.5%). Pedestrians in this age group were most frequently involved in a collision as the result of entering the roadway unexpectedly; that is, running into the roadway or entering the roadway from behind a parked vehicle or object.

* Vehicle defects were reported in 1 percent of the vehicles involved in collisions. It should be noted that the presence of a recorded vehicle defect does not necessarily suggest that it was the proximate cause of the collision.

1985 COMPARED WITH PREVIOUS YEARS

A comparison of the collision statistics for 1985 with those for previous years indicates noticable differences in four areas as follows.

1. Overall Collisions

One hundred and eighteen more collisions (1.6%) occurred in 1985 than in 1984. Consistent with this increase in collisions, the occurrence of injury collisions, persons injured and fatalities in the Region were all higher by between 15.7 percent and 44.4 percent compared to 1984.

2. Bicycle Injuries

The number of people injured in motor vehicle collisions while riding on a bicycle rose from 178 in 1984, to 244 in 1985. For the years 1980, 1981, 1982 and 1983, by comparison, the number of cyclists involved in collisions was 182, 165, 254 and 202 respectively.

3. Pedestrian Collisions Involving Five to Nine Year Olds

Collisions involving five to nine year old pedestrians rose from 51 in 1984 to 86 in 1985, an increase of sixty-nine percent. For comparison, data for the years 1980 through 1983 were 90 collisions, 72 collisions, 107 collisions and 79 collisions respectively.

4. Sixteen to Nineteen Year Old Involvement

The 16 - 19 year old age group of drivers is much less likely to be driving properly when involved in a collision than the overall average. However, in 1985, this age group was involved in fewer collisions per capita than in 1984 and was no more likely to be involved in a collision than the 20 - 24 year old group.

In 1985, sixteen to nineteen year old drivers were involved in fewer motor vehicle collisions following the consumption of alcohol than in 1984. The number of collisions involving 16, 17 and 18 year olds who had been drinking or were impaired was 2, 12 and 18 respectively, versus 4, 14 and 25 respectively in 1984. Since January 1, 1984, the legal drinking age in Ontario has been 19.

Chapter One

Trends

General

Since 1951, the number of motor vehicle collisions and persons injured in motor vehicle collisions in Hamilton and Hamilton-Wentworth has increased (Exhibits 1-4, 1-5, 1-6). However, in the same time period, the population of the reporting area has more than doubled and motor vehicle registrations have risen by a factor of 3 (Appendix Exhibit A-4). There is also evidence to suggest that, with an improving highway system, each registered vehicle is driven a greater distance annually. The effect of increased population, vehicle registration and vehicle use is increased opportunity for motor vehicle collisions to occur.

Normalizing the Data

To fairly assess historical trends, collision data should be expressed in terms of rate (normalized) through the use of one of several factors. Annual motor vehicle use information would provide the most accurate assessment of a motorist's exposure, and hence, likelihood of involvement in a collision. Motor vehicle registration data is somewhat less accurate as a normalizing factor, but is utilized since exposure information is not available. Rates based on registration data should be examined with caution, as the reliability of the registration information is unknown.

Population also provides a suitable and accurate normalizing factor. Exhibits 1-1, 1-2, 1-3 and associated analysis in this chapter refer to data which has been calculated on a population rate basis.

Collisions

The overall motor vehicle collision rate is shown in Exhibit 1-1. As of January 1, 1978, the reporting level for property damage only collisions was raised from \$200.00 to \$400.00. In 1985, the overall number of collisions was 1.6 percent higher than in 1984.

Due to changes in the reporting criteria and reporting area for the period for which historical data are available, trend analysis of the number of collisions would not be appropriate or meaningful.

Collisions (Cont'd)

Personal injury collisions (Exhibit 1-1) show a significant (at the 99 percent level) decline from 1965 to 1985.

The results of this regression analysis and others for data in this chapter are included in Appendix Exhibit A-7.

Injuries

The personal injury rate graph (Exhibit 1-2) parallels the closely related injury collision graph (Exhibit 1-1). From 1951 to 1963, a significant increase in the personal injury rate is noted, while from 1963 to 1985, a slight decrease (statistically significant at the 95 percent level) is shown.

The rate of occurrence of pedestrian injuries (Exhibit 1-2) has demonstrated a modest but consistent decrease from 1951 to 1985.

Fatalities

In 1985, twenty-six persons died in motor vehicle collisions in Hamilton-Wentworth.

Since fatal collisions are rare events, small changes in the number of fatalities cause large fluctuations in the fatality rate (Exhibit 1-3). These fluctuations reduce the validity of statistical tests. Thus while the fatality rate for all collisions shows a slight downward trend, especially since 1968, this trend is not statistically significant. The overall fatality rate thus appears unchanged during the past 35 years. Comparable patterns are evident for Ontario and Canada (Appendix Exhibit A-5).

The fatality rate for pedestrians does display a reduction which is significant over the last 35 years.

Alcohol Involvement

When viewed as a proportion of overall collisions, statistics pertaining to alcohol involvement have remained quite constant over the period 1977-1985. The percentage of collisions in which one or more drivers was reported to have consumed alcohol has averaged approximately 11 percent. Over 22 percent of fatal collisions over the nine year period involved a drinking driver. The proportion of all drivers who had been drinking or were impaired when involved in a collision has dropped from 8.3 percent in 1978 to 5.3 percent in 1985 (see Exhibit 3-6). In 1985, 16 - 20 year olds comprised 8.1 percent of the Hamilton-Wentworth population and were involved in approximately 13 percent of collisions after consuming alcohol.

The first of these is the fact that the collision was not a simple one. It was a complex event involving a number of factors, including the speed of the vehicles, the angle of impact, and the condition of the road. The second factor is the fact that the collision occurred in a busy area, with many other vehicles and pedestrians nearby. This made it difficult for the police to investigate the accident and to identify the cause. The third factor is the fact that the collision occurred at night, which made it even more difficult for the police to investigate the accident.

The police have been working hard to investigate the accident and to identify the cause. They have been looking at the evidence and trying to piece together what happened. They have also been talking to the witnesses and trying to get their accounts of what happened. The police have been working very hard and they are hoping to find out what happened as soon as possible.

(a) Reporting area expanded to include new areas patrolled by the Hamilton-Wentworth Regional Police.

Chapter Two

Selected

Characteristics

Injuries

Of the 21,405 persons involved in collisions, 4,529 received injuries. The chance of an involved person sustaining an injury in a collision varied from a 18 percent chance for a motor vehicle rider or passenger to a 100 percent chance for a pedestrian (Exhibit 2-1). Although the risk of injury would appear to be significantly higher for motorcyclists, bicyclists and pedestrians, this phenomenon is partially or wholly explained by the reporting criteria. It is unlikely that a cyclist or pedestrian would be involved in a collision that resulted in over \$400.00 damage without the cyclist or pedestrian being injured. Small or exposed vehicles such as bicycles also afford less protection in a collision.

Seatbelts

Although motor vehicle seatbelts were reported as being in use for 92 percent of involved drivers (Exhibit 2-2), field observations taken by the Province of Ontario in 1978 (2.1) suggest an actual usage rate for drivers in the order of 65 percent. This discrepancy could be interpreted to mean that a higher proportion of seatbelt users were involved in collisions, but is more likely to indicate an over-statement of seatbelt usage by persons involved in collisions. The involved individual may be concerned about receiving a summons for failure to wear his or her seatbelt or may be concerned about additional financial or civil responsibilities caused by failure to wear belts at the time of the collision.

Motorcycle Injuries

Eighty-seven percent of motorcyclists involved in collisions received injuries, compared to 21 percent of all persons involved in collisions. This is indicative of the limited protection afforded to motorcycle riders involved in a collision.

Fifty-one of 259 (20%) motorcyclists involved in collisions were reported as not wearing helmets, despite the Provincial law mandating helmet use (Exhibit 2-3).

Motorcycle Injuries (Cont'd)

Helmet use did not appear to have an effect on the likelihood of a motorcyclist being injured in a collision. Helmets are intended to prevent head injury, but in a serious collision, the motorcycle rider is equally likely to receive injuries to other parts of the body.

Damages

Total damages in collisions in Hamilton-Wentworth amounted to a sum of approximately 17.4 million dollars (Exhibit 2-4), which includes damage to vehicles and property but does not include medical and hospital expenses, loss of income, or loss of future earnings. The estimated cost of property damage of each collision was \$2,368 with 63 percent of the vehicles involved sustaining damage in excess of \$600 (Exhibit 2-5). When the costs of medical attention, lost income and other effects are considered, the total cost of each collision may exceed \$6,268 (2.3).

Times of Occurrence

A close similarity between the occurrence of collisions and traffic volumes, on a time of day basis (Exhibit 2-6), was observed. However, the collision rate (in terms of traffic volume) was greater than the daily average during the period from midnight to 5 a.m., when 633 or 8.7 percent of all collisions occurred.

The pattern of collision occurrences by time of day and day of week was summarized (Exhibit 2-7 and Exhibit 2-8), and distinct differences were found in the pattern of collision occurrence.

The explanation for variations in patterns of collisions by time of day and day of week may be associated with difference in travel patterns which change during the week due to the frequency of shopping or personal trips, or with psychological factors such as different drinking and stress patterns that might influence collision involvement.

Times of Occurrence (Cont'd)

The pattern of collision occurrences was compared on a month of year basis (Exhibit 2-9) and there was a difference between the number of collisions which occurred each month. The higher number of collisions occurring during the winter months is probably primarily due to drivers not adjusting to adverse weather and roadway conditions.

Impact Types

The type of initial impact was compared with the injury classification of the collisions (Exhibit 2-10) and it was determined (at the 95 percent level) that the probability of injury was not the same for all initial impact types.

The chance of being injured in a single motor vehicle or approaching vehicle collision was 51 to 56 percent compared to a 24 to 53 percent chance for other collision types. However, fewer approaching and single motor vehicle collisions resulted in injuries or fatalities (772 versus 2,402) than other collision types.

Greater than one half of all collisions were in intersections or associated with intersections (Exhibit 2-11). Twenty-seven percent of collisions occurred at signalized intersections, and 24 percent at stop- or yield-controlled intersections (Exhibit 2-12).

Forty-eight percent of all collisions occurred at locations with no form of traffic control.

REFERENCES

- 2.1 Based on surveys conducted by the Ministry of Transportation and Communications of Ontario, July 1978.
- 2.2 Ontario Ministry of Health: The cost of hospital and medical treatment for a person injured while wearing seatbelts is \$282; for those not wearing belts, \$419.
- 2.3 J. J. Lawson, in "The Cost of Road Accidents and Their Application in Economic Evaluation of Safety Programs" estimated that, in 1978, the average cost of a motor vehicle collision was \$4,500.00 for the direct costs of property damage, lost productive work and health care costs only. The 1978 cost was adjusted to \$3,593.00 to more accurately reflect the severity and type of collisions which occur in Hamilton-Wentworth. Based on the Consumer Price Index, the comparable value for 1985 is \$6,268.00 per collision.

Chapter Three

Drivers

Driver Age

Although sixteen to nineteen year olds make up only 5.5 percent of the licenced driving population, this age group was involved in 9.4 percent of reported collisions (Exhibit 3-1). The highest rate of any age group.

Drivers under 21 years of age involved in a collision were recorded as driving properly less than 50 percent of the time. The most frequent improper driving actions recorded for this group were, "failing to yield the right-of-way", "following too close", and "loss of control". (Exhibit 3-2).

Drivers over the age of 65 involved in a collision were recorded as driving properly less than 40 percent of the time. The most frequent improper driving actions recorded for this group were, "failing to yield the right-of-way", "improper turn" and "following too close". (Exhibit 3-2).

Drinking Drivers

Drinking drivers were involved in 8.8 percent of all reported collisions, 23.8 percent of fatal collisions and 11.3 percent of injury collisions (Exhibit 3-3). There was a 33 percent greater chance of an injury occurring in a collision which involved a driver who had been drinking than in a collision in which all drivers were sober. Drivers reported as impaired had relatively constant probability of involvement in injury-causing or property damage only collisions.

Exhibit 3-4 indicates that 41.6 percent of the collisions which occurred during the period from 10 p.m. to 3 a.m. from Wednesdays to Sundays involved drinking drivers.

Exhibit 3-5 indicates that less than 14 percent of the drivers involved in collisions who had been drinking or were impaired were driving properly at the time of the collision and the most frequently indicated improper driver action was loss of control of the vehicle.

Sixteen to nineteen year-olds had the highest probability of being under the influence of alcohol at the time of a collision. Twenty to twenty-four year-olds had the next highest likelihood of being under the influence of alcohol at the time of a collision. (Exhibit 3-6).

Hit and Run Collisions

In 1985, there were 765 hit and run collisions involving 765 hit and run drivers. One hundred percent of hit and run drivers involved in fatal collisions were subsequently apprehended. Forty-one percent of hit and run drivers involved in injury collisions were subsequently apprehended. Seventeen percent of hit and run drivers involved in property damage collisions were subsequently apprehended. (Exhibit 3-8).

Non-Licensed Drivers

The non-licensed driver, including those whose licence was under suspension, was more likely to be involved in a fatal collision (Exhibit 3-9) and also more likely to be under the influence of alcohol at the time of the collision (Exhibit 3-10). The non-licensed driver was also less likely to have been driving properly at the time of the collision (Exhibit 3-11). The most frequent improper driving action of non-licensed drivers involved in a collision was loss of control.

Exhibit 3-12 indicates that 49 percent of the collisions involving a non-licensed driver occurred between 6 p.m. and 6 a.m. whereas only 32 percent of all collisions occurred during this period. The exhibit also indicates that 77 percent of the alcohol-related collisions occurred during this period. The 6 p.m. to 6 a.m. period is characterized by high alcohol involvement, high involvement of non-licensed drivers and high collision involvement rate.

Moving Violations

The Regional Police Department issued over 56,000 moving violation summonses in 1985 and this effort at reducing traffic collisions by selective enforcement is recognized. However, it was determined that, in many cases, enforcement was directed at violations that do not relate proportionately to violations indicated in traffic collisions. This could indicate that the enforcement effort is very successful in that it eliminates collisions of related types. However, this may be an indication that a portion of the enforcement effort is directed at moving violations that are readily enforceable (Exhibit 3-13). It is recognized that some violations involved in colli-

Moving Violations (Cont'd)

sions are difficult to enforce or represent an unfeasible countermeasure to collision occurrences. For example, "following too close" was indicated in 18.7 percent of the improper driving actions and "failure to yield the right-of-way" was indicated in 24.0 percent of improper driving actions. The former is difficult to enforce in the absence of a collision, and it is unfeasible to enforce the latter because proof of failure to yield the right-of-way is only possible in the event of a collision. Selective enforcement nonetheless is a recognized collision countermeasure technique for other types of moving violations.

Motorcycles

The proportion of motorcycle drivers involved in collisions recorded as driving properly is higher than the proportion for other motor vehicle drivers of similar age groups (Exhibit 3-14). This exhibit also indicates that the most frequent improper driver action for motorcyclists was "lost control".

Without more refined data on exposure of motorcyclists in traffic under non-collision circumstances, the significance of a higher proportion of involved motorcycle drivers driving properly in a collision cannot be specifically determined. It could be hypothesized that a motorcycle operator is particularly prone to being involved in a collision when driving properly or alternatively, that the motorcycle operator is particularly adept in avoiding a collision for which he or she would have been responsible.

Bicycles

It was determined that responsibility for a collision involving a bicyclist decreased with increased bicyclist age and that 11.4 percent or less of bicyclists under 15 involved in collisions were recorded as driving properly (Exhibit 3-15). The most predominant known cyclist improper action indicated was "failure to yield the right-of-way" but instances of disobeying other traffic laws were also prominent.

DRIVERS

REPORT OF THE INVESTIGATION

DATE OF INVESTIGATION

On the 14th day of May 1985, at Hamilton, Ontario, the undersigned, a member of the Ontario Provincial Police, conducted an investigation into the collision between a 1981 Ford Taurus and a 1981 Chevrolet. The collision occurred on the 13th day of May 1985, at approximately 10:30 a.m., on Highway 401, between the 10th and 11th mile markers. The Ford Taurus was driven by [Name], and the Chevrolet was driven by [Name]. The collision resulted in damage to both vehicles and no injuries were sustained.

The investigation was conducted by [Name], a member of the Ontario Provincial Police, who was present at the scene of the collision. The investigation was conducted in accordance with the provisions of the Highway Traffic Act, R.S.O. 1980, c. 37, and the Collision Investigation Regulations, O.R.G. 1980, c. 12. The investigation was conducted in accordance with the provisions of the Highway Traffic Act, R.S.O. 1980, c. 37, and the Collision Investigation Regulations, O.R.G. 1980, c. 12.

The investigation was conducted by [Name], a member of the Ontario Provincial Police, who was present at the scene of the collision. The investigation was conducted in accordance with the provisions of the Highway Traffic Act, R.S.O. 1980, c. 37, and the Collision Investigation Regulations, O.R.G. 1980, c. 12. The investigation was conducted in accordance with the provisions of the Highway Traffic Act, R.S.O. 1980, c. 37, and the Collision Investigation Regulations, O.R.G. 1980, c. 12.

The investigation was conducted by [Name], a member of the Ontario Provincial Police, who was present at the scene of the collision. The investigation was conducted in accordance with the provisions of the Highway Traffic Act, R.S.O. 1980, c. 37, and the Collision Investigation Regulations, O.R.G. 1980, c. 12. The investigation was conducted in accordance with the provisions of the Highway Traffic Act, R.S.O. 1980, c. 37, and the Collision Investigation Regulations, O.R.G. 1980, c. 12.

CYCLISTS UNDER 15 WERE MOST LIKELY TO BE DRIVING
IN A MANNER THAT VIOLATED BASIC RULES OF THE ROAD.

General

In 1985, there were 408 pedestrian collisions resulting in 405 pedestrian injuries, and 3 fatalities. This represents a 28 percent increase in the total number of pedestrian collisions and a 50 percent reduction in fatalities of pedestrians involved in collisions.

Age

The relationship between the Regional population distribution and pedestrian involvement in collisions in 1985 was reviewed (Exhibit4-1). It was determined that 5 to 9 year old pedestrians had a rate of collision involvement approximately 3.2 times that expected when compared on the basis of the age distribution of the Regional population.

The variations in rate might be explained by certain pedestrian age groups crossing streets more frequently than others (i.e.exposure). It is, however, unlikely that the 5 to 9 year old group would have different exposure to traffic than the 10 to 14 year old group, and, therefore, the 5 to 9 year old pedestrian would appear to be considerably more prone to collision involvement.

Pedestrian Action

Exhibit 4-2 indicates the pedestrian action at the time of the collision versus pedestrian age. In general, the instances of unsafe pedestrian action for pedestrians involved in collisions were greater for pedestrians under 15 years of age.

This exhibit also indicates that the actions of "coming from behind a parked car" or "unexpectedly running into the roadway" accounted for 24.8 percent of the pedestrian actions at the time of the collisions. These unsafe actions are particularly associated with pedestrians under 15 years of age.

Pedestrian Action (Cont'd)

Examination of the data for pedestrian collisions at traffic signals indicates that pedestrians under the age of 20 were more likely to be involved in a collision as a result of their own unsafe action. (Exhibit 4-3).

In 61 percent of all pedestrian collisions recorded as proceeding with unsafe action, and in 54 percent of pedestrian collisions at traffic signals the pedestrian was recorded as proceeding properly.

Time of Collision

An analysis was performed on the time of day of collisions compared to pedestrian age (Exhibit 4-4) and it was determined that 33.3 percent of pedestrians were injured in collisions which occurred between 3 p.m. and 6 p.m. Fifty children between 5 and 14 years of age were involved in pedestrian collisions which occurred at school crossing times.* This represents 12.3 percent of the 408 pedestrians involved in collisions in 1985 or 41 percent of all involved 5 - 14 year olds. Of the 50 school age children involved, 11 were crossing at traffic signals.

* School crossing times: 8:00 a.m. - 9:15 a.m., 11:30 a.m. - 1:45 p.m., 3:30 p.m. - 4:45 p.m., Monday - Friday; excluding June, July and August.

Pedestrian Condition

In most cases, the condition of the pedestrian involved in the collision was reported as normal. However, in approximately 8 percent of the collisions involving pedestrians, the pedestrian condition was recorded as "had been drinking" or "impaired" (Exhibit 4-5).

Locations

Exhibit 4-6 compares the age of pedestrians involved in collisions with the type of traffic control. In 46.1 percent of the pedestrian collisions, the collision occurred at a mid-block or other location with no control. For pedestrians under 10 years of age, 60 percent were involved at mid-block or other locations with no control. This is to be expected, as the majority of collisions that involved a young pedestrian resulted from the pedestrian entering the roadway unexpectedly. (Exhibit 4-2).

Driver Action

Exhibit 4-7 indicates that in approximately 56 percent of the motor vehicle- pedestrian collisions, the driver was recorded as driving properly. This figure does not necessarily suggest that the drivers involved in these collisions were totally without blame but does indicate that a majority of pedestrian collisions are associated with improper pedestrian action or lack of awareness of traffic conditions at the time of the collision.

Of the 44 percent of motor vehicle-pedestrian collisions in which the driver was not driving properly, the most frequently recorded driver action was failing to yield the right-of-way (associated with 17 percent of all motor vehicle-pedestrian collisions).

Pedestrian Injuries

Most pedestrians (approximately 83%) suffered only minimal or minor injuries when involved in a collision.

Section 1

Section 1 of the Act defines the term "pedestrian" as a person who is walking, running, or pushing or pulling a wheeled conveyance on a footway or a highway. The definition is broad and includes anyone who is using the highway on foot, whether or not they are carrying a bag or a suitcase. The Act also defines the term "footway" as a path or way for pedestrians, and "highway" as a road or way for vehicles.

Section 2

Section 2 of the Act defines the term "vehicular traffic" as a motor vehicle, a horse-drawn carriage, or a person riding a bicycle. The definition is broad and includes anyone who is using the highway on a vehicle, whether or not they are carrying a bag or a suitcase. The Act also defines the term "motor vehicle" as a vehicle that is propelled by an engine or motor, and "horse-drawn carriage" as a vehicle that is propelled by a horse.

Section 3

Section 3 of the Act defines the term "pedestrian crossing" as a crossing of a highway by pedestrians. The definition is broad and includes any crossing of a highway by pedestrians, whether or not it is a designated crossing. The Act also defines the term "designated pedestrian crossing" as a crossing of a highway by pedestrians that is designated as such by the Council.

Exhibit 4-1

5 - 9 YEAR OLDS WERE INVOLVED IN COLLISIONS AT A RATE MORE THAN THREE TIMES GREATER THAN WOULD NORMALLY BE EXPECTED.

Chapter Five
Vehicles

Chapter Five

Vehicles

Vehicle Type

For drivers involved in collisions, the percentage of drivers driving properly was highest for drivers of conventional buses (Exhibit 5-1). Caution should be exercised when interpreting this exhibit as there is no indication of vehicle exposure.

Vehicle Defects

Vehicle defects were recorded for 163 or approximately 1 percent of the vehicles involved in 1985 collisions (Exhibit 5-2). The most frequently recorded defect was a poor or ineffective vehicle braking system. Although a vehicle defect was recorded, it does not necessarily follow that the defect was the proximate cause of the collision.

Chapter Six

Environment

Environment

Chapter Six

Light Conditions

Exhibit 6-1 indicates that most collisions occurred under clear visibility conditions. Although poor light conditions can make driving difficult, collisions under these conditions are probably associated with drivers failing to adjust properly to changed conditions, particularly those associated with the roadway surface. Exhibit 6-2 indicates that 66.8 percent of the collisions occurred under daylight conditions.

Road Surface

An estimated 57.8 percent of collisions occurred under dry pavement conditions (Exhibit 6-3).

Pavement Markings

In accordance with Exhibit 6-4, 80.0 percent of collisions occurred on marked roadways where the markings were visible. In 83 percent of the cases where the road markings were recorded as not visible or obscured, snow, slush, or ice conditions were also reported. It is important to note that pavement markings that are not visible to the driver are not necessarily associated with collision cause. Further analysis would be necessary to indicate whether or not there was a casual relationship.

Road Character

Exhibits 6-5 and 6-6 show that of collisions occurring at intersections, 62.8 percent occurred at the intersection of two, two-way undivided roads and 85.5 percent occurred at the intersection of two roadways with straight and level alignment.

Road Character (Cont'd)

Exhibits 6-7 and 6-8 show that, for collisions occurring at locations other than intersections, 76.6 percent occurred on two-way undivided roadways and 79.5 percent occurred on straight and level alignment.

As normalizing data such as the percentages, various categories of intersections and the traffic volumes passing through those intersections is not presently available, it is not possible to state that one intersection type is less prone to collision occurrence than another. However, the reader is referred to Exhibit 7-4 in regard to signalized intersections and Exhibit 7-7 in regard to arterial roadway sections.

Road Location and Traffic Control

Exhibit 6-9 indicates that the greatest number of collisions occurred at non-intersection locations. If the intersection-related and in-intersection categories are combined, there were a greater number of collisions directly or indirectly related to intersections. As the exposure to vehicle conflicts is inherently greater at intersection locations, this result is not unexpected.

Exhibit 6-10 indicates that collisions occurring at signalized intersections have approximately the same chance of resulting in serious injury than do collisions occurring at stop-or yield-controlled intersections, or locations with no control.

Exhibit 6-11 indicates that the measured point of impact of 51.4 percent of all collisions was within nine metres of the curb lines of an intersection. 27.4 percent of collisions occurred at signalized intersections, and 10.0 percent of collisions occurred within nine metres of intersections with no formal control.

Road Condition

An estimated 98 percent of roads were in good condition at the time of the collision (Exhibit 6-12). Although some roadways were under construction or under repair in the vicinity of the collision, this does not directly imply that road condition was a contributing cause of the collision.

Fixed Objects

There were 1,060 recorded cases where vehicles struck fixed objects adjacent to the road (Exhibits 6-13 and 6-14). Twenty-five percent of the fixed objects struck by vehicles were rigid poles. In 70 percent of all fixed object collisions, a single motor vehicle left the roadway and struck a roadside object as its primary impact. In the remaining cases (30 percent), it would appear that the fixed object was struck after impact with another vehicle or pedestrian.

The chances of injury or death occurring were higher in collisions involving two or more vehicles in which a fixed object was struck than in single motor vehicle fixed object collisions. This may reflect the different nature of the types of collisions.

Eight collisions in which a fixed object was struck resulted in fatalities. This frequency is approximately three times the rate of occurrence of fatalities in collisions in which no fixed object was involved.

the first of these is the fact that the collision was not a simple one. It was a complex one, involving a number of factors, including the weather, the speed of the ships, and the actions of the crew.

The second factor was the weather. At the time of the collision, the weather was very poor. There was a heavy rain, and the visibility was very low. This made it difficult for the ships to see each other, and it was a major factor in the collision.

The third factor was the speed of the ships. Both ships were traveling at high speeds at the time of the collision. This made it difficult for them to stop or maneuver in time to avoid each other.

The fourth factor was the actions of the crew. There were several errors made by the crew of both ships, which contributed to the collision. These errors included miscommunication, poor decision-making, and a failure to follow standard procedures.

In conclusion, the collision was the result of a combination of factors. The weather, the speed of the ships, and the actions of the crew all played a role in the accident. It is important to learn from this accident to prevent similar accidents in the future.

Curb	2	55	39	96	59.4
Crash Cushion	-	-	3	3	-
Building or Wall	1	24	25	50	50.0
Other	-	50	74	124	40.3
Total	8	451	601	1,060	43.3
Single Motor Vehicle Collisions	5 0.7%	296 39.8%	442 59.5%	743 100.0%	
Collisions Involving Two or More Vehicles	3 0.9%	155 48.9%	159 50.2%	317 100.0%	

THE PROBABILITY OF INJURY OR DEATH IS HIGHEST FOR COLLISIONS IN WHICH A ROCK FACE IS HIT.

THE CHANCE OF INJURY OR DEATH IN A COLLISION IN WHICH A FIXED OBJECT IS HIT IS HIGHER WHEN TWO OR MORE VEHICLES ARE INVOLVED.

FIVE SINGLE MOTOR VEHICLE COLLISIONS IN WHICH FIXED OBJECTS WERE STRUCK RESULTED IN FATALITIES.

Chapter Seven

Locations

General

Locations that have high numbers or rates of collision occurrences have received regular attention by roadway authorities in the Region and countermeasures are constantly being implemented on existing facilities and incorporated into the design of new facilities. However, physical alterations are not effective in preventing the majority of traffic collisions as these are the direct result of driver or pedestrian error.

Area Municipality

In general, the collision rate increased with increasing municipality size (Exhibit 7-1).

High Frequency Intersection Locations

Exhibit 7-2 represents a list of the 71 locations which experienced the highest number of collision occurrences in 1985. All 1985 collisions occurring at traffic signals were subjected to the control chart analysis technique (Exhibit 7-3). Additional information including collision data from previous years is included with this exhibit.

Exhibit 7-4 shows the relative number of collisions and collision rates for selected groups of signalized intersections.

These exhibits do not necessarily represent priority lists for improvements as other factors have to be taken into account such as cost-benefit considerations or the deployment of other countermeasure opportunities which may be more cost-effective.

In many cases, these locations are already under consideration for various forms of improvement on a priority basis.

High Frequency Road Section Locations

Exhibits 7-5, 7-6 and 7-7 portray arterial roadway sections within the City of Hamilton which have the highest collision rates. The criteria for reporting is collisions per million vehicle kilometres travelled per annum. Exhibit 7-5 evaluates roadway sections including all collisions along the roadway. Exhibit 7-6 demonstrates collision rates on roadway sections excluding collisions occurring within 9 metres of a signalized intersection. Exhibit 7-7 shows collision rates on roadway sections excluding collisions occurring at all intersections, signalized or non-signalized. Exhibit 7-8 presents a summary of collision rates for selected groups and subcategories of the arterial system.

The trends over the past nine years are interesting to note when reviewing Exhibit 7-7. As the overall number of collisions within the City of Hamilton and Region has been dropping since 1977, with traffic volumes relatively constant, collision rates on roadway sections show a parallel decline.

Exhibit 7-1

COLLISIONS VS AREA MUNICIPALITY

Municipality	<u>Class of Collision (a)</u>				1985 Collision Rate per 1,000 Pop.(b)
	Fatal	Non-Fatal Injury	Property Damage Only	All Collisions	
Ancaster	1	79	116	196	11.8
Dundas	1	99	152	252	12.5
Flamborough	3	111	185	299	11.7
Glanbrook	1	41	62	104	11.0
City of Hamilton	14	2,541	3,315	5,870	19.1
Stoney Creek	1	282	342	625	14.9
Total for the Regional Municipality of Hamilton- Wentworth	21	3,153	4,172	7,346	17.4

COLLISION RATE IN TERMS OF COLLISIONS PER
1,000 POPULATION GENERALLY INCREASED WITH
INCREASED MUNICIPALITY SIZE.

(a) Collisions reported to the Hamilton-Wentworth Regional Police only; areas patrolled by the Provincial Police (e.g. Kings Highways) are not included.

(b) 1985 Regional Assessment Office population figures used.

Exhibit 7-2

INTERSECTIONS WITH HIGHEST NUMBER OF COLLISIONS IN 1985 (a)

Intersection	Type of Traffic Control	Number of Collisions	5 Yr. Average

(1) A 1-Year Average

(2) A 2-Year Average

(3) A 3-Year Average

NOTES:

(a) RL is the number of collisions per million vehicles entering within 31 feet of an individual intersection in 1985.

(b) RC is a volume-adjusted critical rate. If RL exceeds $\text{RC} \left(\text{i.e. } \frac{\text{RC}}{\text{RC}} \right)$ is greater than 1.00, one can state with 95 percent confidence that the collision rate at the intersection in question is significantly higher than would normally be expected.

$\text{RC} = \text{Ra} + \text{K} \quad \text{Ra} = \frac{0.5}{m}$ where Ra = systemwide average collision rate for all traffic signal locations (0.66 collisions per million vehicle entries in 1985.)

K = constant = 1.65 (for 95% confidence level)

m = vehicle exposure at the location in million vehicles entering per year $\left(\frac{\text{AADT} \times 349.6}{106} \right)$

(c) AADT - Average Weekday Daily Traffic; AADT - Average Annual Daily Traffic.

Exhibit 7-4

**OVERALL COLLISION RATES
FOR SELECTED GROUPS OF SIGNALIZED INTERSECTIONS**

<u>Intersections Included</u>	<u>Data for 1985 Only</u>		<u>Data for 1981-1985</u>	
	<u>Avg. No. of Collisions Per Year</u>	<u>Rate (Collisions/ Million Vehicles Entering)</u>	<u>Avg. No. of Collisions Per Year</u>	<u>Rate (Collisions/ Million Vehicles Entering)</u>
All intersections	4.94	0.60	5.41	0.66
Intersections of one-way streets with one-way streets	4.83	0.56	5.56	0.64
Intersections of one-way streets with two-way streets	3.96	0.48	4.37	0.53
Intersections of two-way streets with two-way streets	5.31	0.66	5.67	0.71
Central business district intersections	4.96	0.57	5.44	0.62
C.B.D. fringe or industrial intersections	4.81	0.59	5.15	0.63
Suburban shopping-type intersections	5.82	0.63	6.46	0.70
Residential area intersections	4.01	0.57	4.30	0.61
All lower city intersections	4.93	0.58	5.39	0.63
All mountain intersections	5.26	0.70	5.93	0.79

THERE HAVE BEEN NO MARKED CHANGES IN THE OVERALL COLLISION RATES FROM 1984 TO 1985. HOWEVER, THERE HAVE BEEN SOME CHANGES IN THE INDIVIDUAL SUBSECTIONS.

Exhibit 7-5

NOTES: Re: Collision Rates on Roadway Sections

- (a) Exhibit 7-5 includes all collisions on an arterial roadway section. If the roadway section ends at an intersection, signalized or unsignalized, one-half the number of collisions occurring at the intersection is included.
- (b) Exhibit 7-6 includes all collisions on an arterial roadway section excluding those which occur within nine metres of a signalized intersection. If the roadway section ends at an unsignalized intersection, one-half the number of collisions occurring at the intersection is included.
- (c) Exhibit 7-7 includes only collisions on an arterial roadway section which occur greater than nine metres from any intersection. That is, no collisions referenced to an intersection, signalized or unsignalized, are included.
- (d) R_L is the collision rate for the roadway section expressed as collisions per million vehicle kilometres travelled per annum.
- (e) R_C is a volume-adjusted critical rate. If R_L exceeds R_C (i.e. $\frac{R_L}{R_C}$ is greater than 1.00), one can state with 95 percent confidence that the collision rate for the roadway section in question is significantly higher than would normally be expected.

$$R_C = R_a + K \sqrt{\frac{R_a}{m} - \frac{0.5}{m}}$$

where R_a = systemwide average collision rate for all roadway sections (3.53 collisions per million vehicle kilometers in 1981-1985 for Exhibit 7-5; 2.42 collisions per million vehicle kilometres in 1981-1985 for Exhibit 7-6; 1.49 collisions per million vehicle kilometres in 1981-1985 for Exhibit 7-7).

K = constant = 1.65 (for 95% confidence level)

m = vehicle exposure for the individual roadway section in million vehicle kilometres per year
 $(\text{AWDT} \times \frac{349.6 \times \text{Section Length}}{10^6})$

- (f) AWDT - Average Weekday Daily Traffic

Exhibit 7-8

**ARTERIAL ROADWAY SECTIONS
COLLISION RATES
FOR SELECTED GROUPS**

<u>Category</u>	Collision Rate (Collisions Per Million Vehicle Kilometres)		
	<u>Including All Intersections</u>	<u>Signalized Intersections Not Included</u>	<u>Intersections Not Included</u>
All Arterials 1985	3.53	2.42	1.49
All Arterials 1984	3.34	2.31	1.42
All Arterials 1983	3.34	2.30	1.38
All Arterials 1982	3.59	2.47	1.48
All Arterials 1981	4.04	2.69	1.66
All Arterials 1980	4.00	2.65	1.61

NOTES:

- (a) Registration is for all vehicles including passenger and commercial vehicles, buses, motorcycles and mopeds.
- (b) Data not available. Estimated from provincial value.
- (c) Estimated by the Ministry of Transportation and Communications.
- (d) Data estimated from provincial value for City of Hamilton only.
- (e) From 1973 on, population figures are for the Regional Municipality of Hamilton-Wentworth.
- (f) For City of Hamilton only.
- (g) R. L. Polk estimate for Region of Hamilton-Wentworth for 1975 - 180,084.
- (h) Ministry of Transportation and Communications estimate for Region based on licence sales only, for Regional Hamilton-Wentworth.
- (j) For Regional Municipality of Hamilton-Wentworth.
- (k) Ministry of Transportation and Communications figures includes active, inactive, unfit, wrecked, out-of-province and sold vehicles.

Exhibit A-7

TRENDS DATA
REGRESSION EQUATIONS

Statistic	Years	Equation (a)	Significant Slope at 95%	99% (b)	Range of Significant Slope at 95%
1. Collision Rate - All (c)	1951-1985	$y = -0.232 x + 30.16$	Yes	No	-0.616 to 0.151
2. Collision Rate - All (c)	1965-1985	$y = -0.884 x + 34.54$	Yes	Yes	-1.187 to -0.581
3. Injury Collision Rate	1954-1985	$y = 0.069 x + 6.49$	Yes	No	-0.042 to 0.181
4. Injury Collision Rate	1965-1985	$y = -0.131 x + 9.82$	Yes	Yes	-0.229 to -0.033
5. Personal Injury Rate	1951-1985	$y = 0.180 x + 6.83$	Yes	Yes	0.031 to 0.329
6. Personal Injury Rate	1963-1985	$y = -0.113 x + 13.19$	Yes	Yes	-0.270 to 0.044
7. Pedestrian Injury Rate	1951-1985	$y = -0.034 x + 2.26$	Yes	Yes	-0.052 to -0.015
8. Fatality Rate - All Collisions	1951-1985	$y = -0.103 x + 10.52$	Yes	No	-0.269 to 0.063
9. Pedestrian Fatality Rate	1951-1985	$y = -0.130 x + 6.75$	Yes	Yes	-0.228 to -0.032

(a) The variable "x" represents the year; "y" the number of collisions expected.
"x" is 1.0 for the first year included in the equation.

"y" is in collisions per 1,000 population for 1 and 2; in injuries per 1,000 population for 3, 4 and 5; and in fatalities per 100,000 population in 6 and 7.

(b) If the slope of the regression line is significant, it can be stated with the indicated level of confidence that the slope is not equal to zero.

(c) Includes changes in reporting criteria and reporting area. For this reason, caution should be exercised in drawing any conclusions drawn from this regression line.

(1) KEY TO CRITERIA FOR REPORTING COLLISIONS (Seen next page for definition of injury collisions)

It is generally assumed, unless otherwise noted, that only collisions occurring on public roadways involving personal injury or property damage greater than the reporting level are included on this table.

- (a) Collisions reported involving an infraction of the Provincial Highway Traffic Act with property damage only and less than reporting level.
- (b) Collisions reported involving an infraction of the Criminal Code of Canada with property damage only and less than reporting level.
- (c) Hit and run collisions reported with property damage only and less than reporting level.
- (d) Collision reported if it involves any personal injury.
- (e) Public property damage collisions.
- (f) Collisions involving City or Regional government vehicles.
- (g) "With the introduction of amicable constat by insurance companies in July, 1979, a great number of accidents with material damages are not reported and are out of control".
- (h) estimated.
- (2) Only injuries requiring medical attention were classified as injury collisions.
- (3) Injury collisions do not include fatal accidents.
- (4) Not including Regional roads or kings highways.

DEFINITIONS OF "PERSONAL INJURY" (a)

Regional Hamilton-Wentworth	- any bodily harm, visible or complained of, that results from a motor vehicle collision.
City of Hamilton	- any bodily harm, visible or complained of, that results from a motor vehicle collision.
Burlington	- any bodily harm, visible or complained of, that results from a motor vehicle collision.
Calgary	- any type of injury resulting from a collision.
Edmonton	- including minor abrasions and bruises, complaint of pain, caused by a motor vehicle collision.
Halifax	- injury or death (no stipulation regarding severity of injury) caused by a motor vehicle collision.
London	- any type of injury, visible or complained of, caused by a collision; need not be treated at a hospital.
City of Montreal	- any injury, apparent or not, to any person, caused directly or indirectly, by a motor vehicle.
Regional Ottawa-Carleton	- injury is any bodily harm visible or complaint of, caused by a motor vehicle collision.
City of Regina	- any bodily harm, visible or complaint of, caused by the accident.
Saskatoon	- any bodily harm, visible or complaint of, caused by a collision.
Metro Toronto	- injury must be reported when an injury occurs to any of the involved persons in a collision.
Vancouver	- up to discretion of driver or police if in attendance.
Windsor	- any injury resulting from a motor vehicle collision.
Winnipeg	- readily identifiable injury or perceived injury caused by a collision.
Region Halton	- same as Burlington.

DEFINITIONS OF "PERSONAL INJURY" (a) CONTINUED

Mississauga	- N/A
St. Catharines	- any type of injury resulting from a collision.
Regional Niagara	- any type of injury resulting from a collision.
Regional Waterloo	- injury or death (no stipulation regarding severity of injury) caused by a motor vehicle collision.

- (a) definitions of a "personal injury" such that a collision involving a personal injury must be reported.
